

PROJECT DEVELOPMENT AND EVALUATION RESOURCES

The Program Plan provided a high-level summary of the recommended methodology for developing and evaluating projects based on safety, mobility, facility type, and weather needs. The following sections provide detailed process information about how the data was retrieved and analyzed for this effort. The data has been prepared for this annual process, however, it is recommended that the data be refreshed each year prior to the project development cycle. The methodology has been developed to be data driven and user friendly. In addition, consideration has been given to the limited anticipated resources available to implement the annual data refresh requirements.

SAFETY

ALDOT's Safety Operations Program regularly updates crashes as a part of their database. The data is available through an online dashboard called *Advance*. It was established by the Alabama Criminal Justice Information Center (ACJIC) to provide safety information using analytic and visualization technologies. The data originates from Critical Analysis Reporting Environment (CARE) and organizes it through a Dataset ID (eCrash) and Dataset Name (Alabama Integrated Crash Data). The crash information used for this analysis dates from January 2013 to February 2019.

Based on the data acquired using *Advance*, crash information can be pulled by county and categorized into crash type, including: fatal, incapacitating, non-incapacitating, possible injury, property damage only, unknown. The recommended crash evaluation methodology uses the national and statewide fatal crash rate to compare county-level and project-level areas. Based on the 2016 Crash Facts report prepared by ALDOT and the *Drive Safe Alabama* campaign, the national and statewide crash rates are shown in Table A1.

Table A1: Crash Totals and Rates (2012-2016)

Source: Alabama Department of Transportation, 2016 Crash Facts (<http://www.caps.ua.edu/files/2018/02/ALDOT-2016-CrashFactsBook.pdf>)

Crash Totals and Rates (2012-2016)					
Year	Total Crashes	Total Injuries	Total Fatalities	Alabama Fatality Rate (Per HMVM*)	National Fatality Rate (Per HMVM*)
2012	128,307	40,202	870	1.34	1.14
2013	126,862	37,559	852	1.31	1.10
2014	133,219	39,518	821	1.24	1.08
2015	147,452	44,020	849	1.24	1.13
2016	155,907	47,653	1089	1.56	1.19**

*Hundred Million Vehicle Miles

**This value has been updated to reflect the final 2016 fatality rate as the report was released 9 months into the year and reflected an intermittent value.

FATALITY CRASH RATE CALCULATION

The following methodology is based on the expectation that a given project is corridor based, if a project is not corridor based, it is recommended that the Evaluation Committee determine potential safety impact on a case by case basis. Fatality crash rates for the specific projects are compared to the nationwide and statewide crash rates for scoring purposes. The fatality crash rates for each project should be calculated using data from *Advance*. The fatality crash rate will then be used during project evaluation and prioritization. The fatality crash rate is a three-step calculation.

Step 1 – Proposed Project Crash Data

The first step is used to determine the number of fatalities along the project segment and sum them for the past five years. The user should log into *Advance* using ALDOT credentials. The homepage is shown in the figure below.

Homepage of Advance

Upon logging in, the user will use the map to identify where in the project corridor is located. The dashboard has the capability for one to draw a polygon around the area of interest (in this case the project corridor) and can be used to pull project area specific data. After drawing a polygon around the project corridor, click on the “drill down” tab on the left panel which will display data for the polygon drawn. An example of the map interface is shown below.

Crashes in and around AL-8 and Auburn University

The user will then record these statics and move on to the next step of the calculation.

Step 2 - MVM

The second step is used to calculate the project segment million-vehicle-miles (MVM). The following formula is used to calculate MVM for each project that is corridor based. If a project is not corridor based, it is recommended that the Evaluation Committee determine potential safety impact on a case by case basis.

$$MVM = \frac{AADT * \times segment\ length * 365 * number\ of\ years **}{1,000,000}$$

*AADT stands for Annual Average Daily Traffic and can be determined by referencing ALDOT's AADT GIS Shapefile (which is updated annually)

**Number of years references total number of years that the crash data has been pulled. It has been recommended that data be retrieved for the previous five years, thus equal to five.

Step 3 – Project Fatality Crash Rate

The third step is used to calculate the fatality crash rate using the calculations in step 1 and 2.

The project segment fatality crash rate is determined by the following equation:

$$\text{Project Segment Fatality Crash Rate} = R = \frac{\text{Number of Fatal Crashes in the } n \text{ Year Period} *}{\text{MVM for the } n \text{ Year Period}}$$

*Number of crashes references the sum of the fatal crashes that occurred within the n Year Period (in this case, it is recommended to continue with the five-year timeline).

PROJECT EVALUATION

Alabama's fatal crash rate has consistently been above the national average. Furthermore, ALDOT is committed to reducing the number of fatalities on their roadways regardless of the national average. Therefore, emphasis has been given to those projects that are expected to positively impact safety in areas with fatal crash rates above the statewide and national averages.

It is recommended that the calculated project fatal crash rate be compared to the national and statewide average fatal crash rates and assigned points based on the table below.

Table A2: Crash Evaluation

Reference for annual fatality rates (nationwide and statewide): National Highway Traffic Safety Administration (USDOT)
<https://cdan.nhtsa.gov/SASStoredProcess/guest>

SAFETY EVALUATION SCORING			
Scoring Tiers	Comparison		Score
Low	Fatality crash rate is less than the national fatality rate (1.15% in 2017)	$R < 1.15$	1
Medium	Fatality crash rate is between the national fatality rate (1.15% in 2017) and the statewide fatality rate (1.56% in 2017)	$1.15 < R < 1.56$	2
High	Fatality crash rate is higher than the statewide fatality rate (1.56% in 2017)	$1.56 < R$	3

MOBILITY

The following sub-section provide information specific to the data resources, retrieval, and analysis methodology developed to consider the relative need and potential impact of TSMO deployment strategies. All information is provided such that the data and methodology can be recreated, however, efforts were made to create efficiencies such that the annual process of data regeneration would be as efficient as possible.

CONGESTION DATA ANALYTICS

The FHWA provides data to agencies throughout the nation. The data is sourced from the National Performance Management Research Data Set (NPMRDS) which is an archived speed and travel time data set (including associated location referencing data) captured from roadway sensors and probe-based systems that covers the National Highway System (NHS). The Regional Integrated Transportation Information Systems (RITIS) web-based platform was created to aggregate travel times and speed data and provide access to analytics and visualization tools. ALDOT does not currently subscribe to the full version of RITIS; the free version of the platform is available for users to access the NPMRDS with limited tools and has been used for the following methodology.

The platform allows users to access historical and real-time data for a majority of roadways throughout the state of Alabama using data visualization and limited data retrieval tools. These tools allow users to create and download reports, visualize data on maps or in other interactive graphics, and even download raw data for off-line analysis.

RITIS segments the road network into Traffic Message Channels (TMCs). TMC segments are identified using TMC segment codes that consist of three components: an area/region code, a directionality code, and a segment code. TMC segments vary in length throughout the state and have predefined beginning and end points. Through the visualization platforms, routes in RITIS are developed by stitching together multiple TMCs to create segment sets.

CORRIDORS OF REGIONAL SIGNIFICANCE

The TSMO Regional Plans for the Southeast, Southwest, West Central, and East Central regions were used to identify corridors of regional significance. These corridors were built and saved in RITIS as segment sets for analysis. A segment set was created for each route of regional significance identified in the regional plans.

RITIS provides a variety of visualization tools, as shown in the figure below. Routes can be created and saved using most of the tools provided in RITIS, however routes are not always interchangeable between the tools. For example, routes created in the Massive Data Downloader may not be available for analysis in the Congestion Scan tool, depending on the method of creation. For this analysis, the Congestion Scan tool was used which has two methods for creating routes. These methods require users to search by route name and number using the standard and advanced search function. Users can enter in the respective route number or road name to search for the available TMCs that have available data.

Start by selecting *Congestion Scan* from the home page, which redirects user to the main interface (i.e. route selection panel and world map). The map is used to identify TMCs that will be included in the route creation and will display the currently selected TMC segments. Hovering over individual TMC segments provides information to the user such as road name, direction, and TMC segment code, as shown in the figure below.

<https://www.ritis.org/>

Standard Search

Under the *Road* tab, a standard search can be conducted by selecting the state of Alabama, typing in the name of the road, and hitting search. A standard search will bring up all the roads in the state that match the name entered, including roads that have a similar name to the road name entered. This search method may result in a large list of roads and large sets of TMC segments. Additionally, roads that have several names may be listed under another less common name (e.g. US 43 is listed as SR 13). TMC segment road names may also change throughout the corridor.

Congestion Scan Screen Capture

Advanced Search

The advanced search feature can narrow the search by county, directionality, zip code, and roadway classification information to find the correct TMC segments. For example, when I-85 is searched within Montgomery County, only TMC segments that are entirely within the county are returned.

Once the route is selected, parameters such as directionality and length can be manipulated below the search window, highlighted by the green box in the figure below. Corridor length can be updated by selecting a partial set and choosing the start point and end point that best matches the needs of the analysis.

Congestion Scan Screen Capture

To remove TMC segments from the group, left click on the TMC segments on the map and select “*Remove this TMC Segment.*” The option to add the TMC segments back to the group is available until the entire set is removed or the page is refreshed.

Once TMC segments are created using any of the previously described methods, they can be saved by clicking save as *segment set* in the lower right corner. The user should enter the description for their routes and select whether to allow others within their agency to use the TMC set.

Additionally, under *Saved* tab, previously created and saved TMC sets can be accessed and added to the current analysis. Under *Display Options*, saved TMC sets can be filtered by text and owner. To modify a saved TMC set, select an existing TMC set from the available list and add segments using the above listed options or remove segments by left clicking the segment on the map and selecting *Remove this TMC segment*. Saved TMC sets are also editable based on the method that was used to create them. Those created using the search by road feature can be split by direction and into partial segments.

Use of Developed Routes

TMC segment sets have been developed for a majority of the previously mentioned corridors of regional significance. The NPMRDS data set is limited in its coverage area and the corridors with available data are identified below by region:

- Southeast: US 84, SR 167, I-85, US 231, US 331, US 431, US 80, I-65, US 82, US 280, US 29, SR 271, US 31
- Southwest: I-10, US 90, US 31, SR 59, SR 193, SR 163, US 45, US 98, I-65, I-165, US 43, SR 158, US 84, SR 182, SR 1113, SR 287, US 90, US 80, SR 13
- East Central: I-459, I-20, I-65, US 280, US 78, I-22, I-59, SR 21, I-85, US 31, US 11, US 431, US 231
- West Central: I-20/I-59, US 82, SR 118, I-22, US 43, SR 69, SR 215, US 11, SR 13
- North: SR 24, US 431, US 231, US 72, I-565, I-65, US 13

The Massive Data Downloader Tool offers users the ability to create segment sets using known TMC codes. Under the *Segment Codes* tab, multiple TMC codes, separated by commas, can be entered into the provided field. Once the *Add segments* button in the lower right-hand corner is selected, the user has the option to save the TMC set using the same methodology described in the previous section. This method is the quickest way to build a route if the user already has a list built.

Massive Data Downloader Screen Capture

TMC codes for each of the corridors of regional significance are listed at the end of this Appendix as a comma-separated list. These lists can be used to recreate the TMC sets for each route. Please note, this method can only be used to recreate the routes for use in the Massive Data Downloader Tool. The Congestion Scan tool will not list saved TMC sets that were created using lists of TMC codes. The TMC sets will need to be created using either the standard or advanced search function.

TRAVEL TIME INDEX ANALYSIS

Travel time index is defined as the ratio of travel time in a peak period to travel time in free flow conditions. A travel time index of 1.50 would indicate that a 30-minute free flow trip would take 45 minutes in the peak period.

The *Congestion Scan* tool allows users to analyze traffic conditions on one or more stretches of road for a defined time period. Based on user inputs, the Congestion Scan generates a contour plot of traffic conditions. Once the segment set is created or selected from the saved tab, users can define the time period, data source, and granularity of the analysis to be completed. For this analysis a one-year period was chosen, focused on a typical weekday (Tuesday, Wednesday, Thursday), for both trucks and passenger vehicles, returning results in one-hour increments.

The dropdown menu at the top of the page allows the user to control which performance metric is displayed (e.g. historic average speed, travel time index, congestion, etc.). For the purposes of this analysis, travel time index was reported for all study corridors.

2. Select one or more time periods to analyze

Data Selection Screen Capture

The plot generated can be exported as XML file for additional analysis. Users can click on the disk in the upper right-hand corner of the plot to download an XML file containing the raw data in a format similar to the displayed results. The exported XML file can be saved as a standard Excel file or easy manipulation. Once the file is downloaded the data can be averaged across any time interval desired (e.g. AM Peak, PM Peak, etc.).

One year of data was pulled for all corridors from September 2017 to August 2018. The Congestion Scan tool was used to generate reports that averaged travel time index in one-hour increments for a standard weekday over the one-year period. The average travel time index along each corridor was determined. This data was then geo-coded by joining the excel file with a RITIS generated GIS file that has all of the NPMRDS TMC's associated and used to show a comparison of congestion across the state of Alabama visually in the accompanying maps.

Research completed with the University of Alabama was used to determine the threshold values for the maps shown. According to the research paper *Congestion Quantification Using the National Performance*

*Management Research Data Set*¹ (Sisiopiku, Rostami-Hosuri, 2017) the following thresholds were selected to reflect user perceptions of congestion and its impact on their travel times and are summarized as follows:

- $1.10 < \text{TTI} < 1.50$ moderate congestion
- $1.50 < \text{TTI} < 2.00$ significant congestion
- $\text{TTI} > 2.00$ severe congestion

These ranges of travel time indices were used to correlate to Low, Medium, and High congestion needs for both vehicular and freight congestion. These maps are available for use during the project development (B1 and B2) and evaluation phase as described in the Program Plan.

BENEFIT-TO-COST EVALUATION

Benefit-to-cost analysis is used to communicate and consider the anticipated value of a particular project. It is the ratio of expected monetary benefit of a project divided by the cost of the project. There are many different methodologies and varying complexities to consider when calculating benefits.

FHWA has developed a Tool for Operations Benefit Cost Analysis (TOPS-BC) that is sometimes used by agencies to guide in benefit-to-cost analysis. Other agencies develop their own tools to guide users based on agency specific and readily available data. Further still, many agencies focus benefit-to-cost analysis on larger, more complex projects.

However, the basic premise of analysis is similar throughout methodologies; project specific crash and/or congestion data are considered and an expectation of benefit based on research and/or case study evaluations is applied and typically monetized. For example, crashes along a potential project corridor will be considered and an evaluation of a similar project type as to the one being proposed which states a measured reduction of crashes will be applied to the potential project corridor crashes. The projected reduced crashes will then be given an estimated monetary value to represent the potential safety benefit anticipated for the proposed project. Furthermore, this value can then be compared to the estimated cost of the proposed project and reported as a benefit-to-cost ratio which allows projects of different types to be considered.

The following methodology has been developed as a simplified way to consider potential project benefit-to-cost ratios for common project types. This is recommended as a starting point for comparison. It is expected that larger or more unique project types may require more extensive analysis such as TOPSBC or other tools as described above.

SIMPLIFIED BENEFIT-TO-COST ANALYSIS

The variance in need, safety or mobility, is the primary influence on how much value or benefit can be provided by a given project type – simply stated, the bigger the problem, the greater opportunity for improvement. Therefore, the recommended simplified benefit-to-cost analysis considers demonstrated benefit-to-cost ratio ranges within several common project types and assumes there is a direct correlation to the safety and congestion need. The following steps are recommended to evaluate benefit-to-cost for a proposed project.

Step 1 – Project Type Benefit-to-Cost Ratio Ranges

The following table provides a summary of benefit-to-cost ratio ranges that have been published and supported by FHWA for various TSMO strategy types.

<https://ops.fhwa.dot.gov/plan4ops/topsbctool/>

Table A3: Benefit-to-Cost Ratio Ranges

Source: <https://www.itsbenefits.its.dot.gov/ITS/benecost.nsf>

Deployment Strategy	Benefit-to-Cost Range	
	Low (BC _L)	High (BC _H)
Integrated Corridor Management	9.7	39.0
Optimized Traffic Signals	17.0	62.0
DMS Deployment	1.4	16.95
CCTV Camera Deployment	3.95	16.6
Service Patrols (Traffic Incident Management)	4.7	38.0
Warning Systems	4.2	6.6

For the purposes of this simplified analysis, it is assumed that the following deployment strategies represent:

- Integrated Corridor Management – it is assumed that corridor-based deployments of fiber optic cable, CCTV cameras, and signal timing upgrades will fall under this category.
- Optimized Traffic Signals – it is assumed that this deployment strategy will represent those projects in which communications to traffic signals is already established, no further surveillance is required or planned, and the effort is focused solely on the optimization of existing traffic signals.
- DMS Deployment – it is assumed this is for the permanent deployment of a DMS.
- CCTV Camera Deployment – it is assumed that strategic camera deployments or camera only deployments will fall under this strategy type.
- Service Patrols – it is assumed that ASAP expansion will fall under this strategy type.
- Warning Systems – it is assumed that warning systems such as curve, speed, queue, etc. will be considered to fall under this strategy type.

Step 2 – Safety and Mobility Need

Next, as mentioned previously, it is assumed that there is a direct correlation between safety and mobility, and potential benefit received from a project. It is recommended that the safety and mobility score be added to determine a combined relative need factor:

$$\text{Safety Score } (S) + \text{Congestion Score } (C) = \text{Relative Need } (RN)$$

$$S + C = RN^*$$

*Based on the methodology for safety and congestion evaluation scoring above, the minimum score is equal to two and maximum score is equal to 6.

Step 3 – Project Simplified Benefit-to-Cost Ratio

Then the relative need factor (RN) should be applied to the benefit-to-cost range such that the resulting benefit-to-cost is scaled based on the relative need. The following formula should be used to determine the project simplified benefit-to-cost ratio.

$$\frac{1}{4}x(BCH - BCL)x(RN - 2) + BCL = BCP$$

Where: BCH = the benefit-to-cost ratio high range for the specific project deployment strategy type.

BCL = the benefit-to-cost ratio low range for the specific project deployment strategy type.

RN = the relative need as determined in step 2.

BCP = the simplified anticipated benefit-to-cost ratio for the specific project being considered.

Step 4 – Benefit-to-Cost Score

Finally, it is recommended that the benefit-to-cost score be developed annually such that each annual cycle, all of the project benefit-to-cost ratios will be assigned a score between one and three, distributed by how they compare relative to each other. This scoring assignment has been built into the project evaluation tool but is given below for information and transparency.

$$1 + \frac{(BCPx - BCPl)}{BCPh - BCPl} \times 2 = BC \text{ Score}$$

Where: BCPx = the benefit-to-cost for the specific project being considered.

BCPl = the lowest benefit-to-cost ratio determined for the annual cycle of projects.

BCPh = the highest benefit-to-cost ratio determined for the annual cycle of projects.

BC Score = the score representing the benefit-to-cost analysis for the project being considered.

TMC Segment Codes		
Corridor	Limits	TMC Codes
